

Generic MC study of $B^0\bar{B}^0$ oscillation frequency using $D^*\ell\nu$

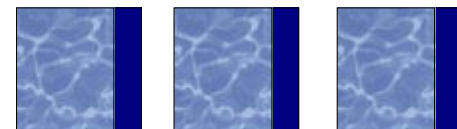

- 1) Data Sample
- 2) Reconstructing $D^*\ell\nu$
- 3) Backgrounds
- 4) Fitting for Δm
- 5) To Do

The purpose of this study is to develop, validate and optimize various tools for the fitting process.

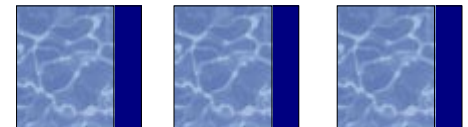

1 Data Sample

1. $\sim 10 \text{ fb}^{-1}$ of $B^0\bar{B}^0$ and B^+B^- generic MC
2. All MC from releases 8.8.0c – 8.8.0i
3. Important parameters from DECAY.DEC
 1. $D_m = .472 \text{ ps}^{-1}$
 2. Lifetime = 1.548 ps
4. Standard DstarlnuUser ntuples are converted to root tuples and final cuts are applied. The resulting root file is similar to "ASCii" files

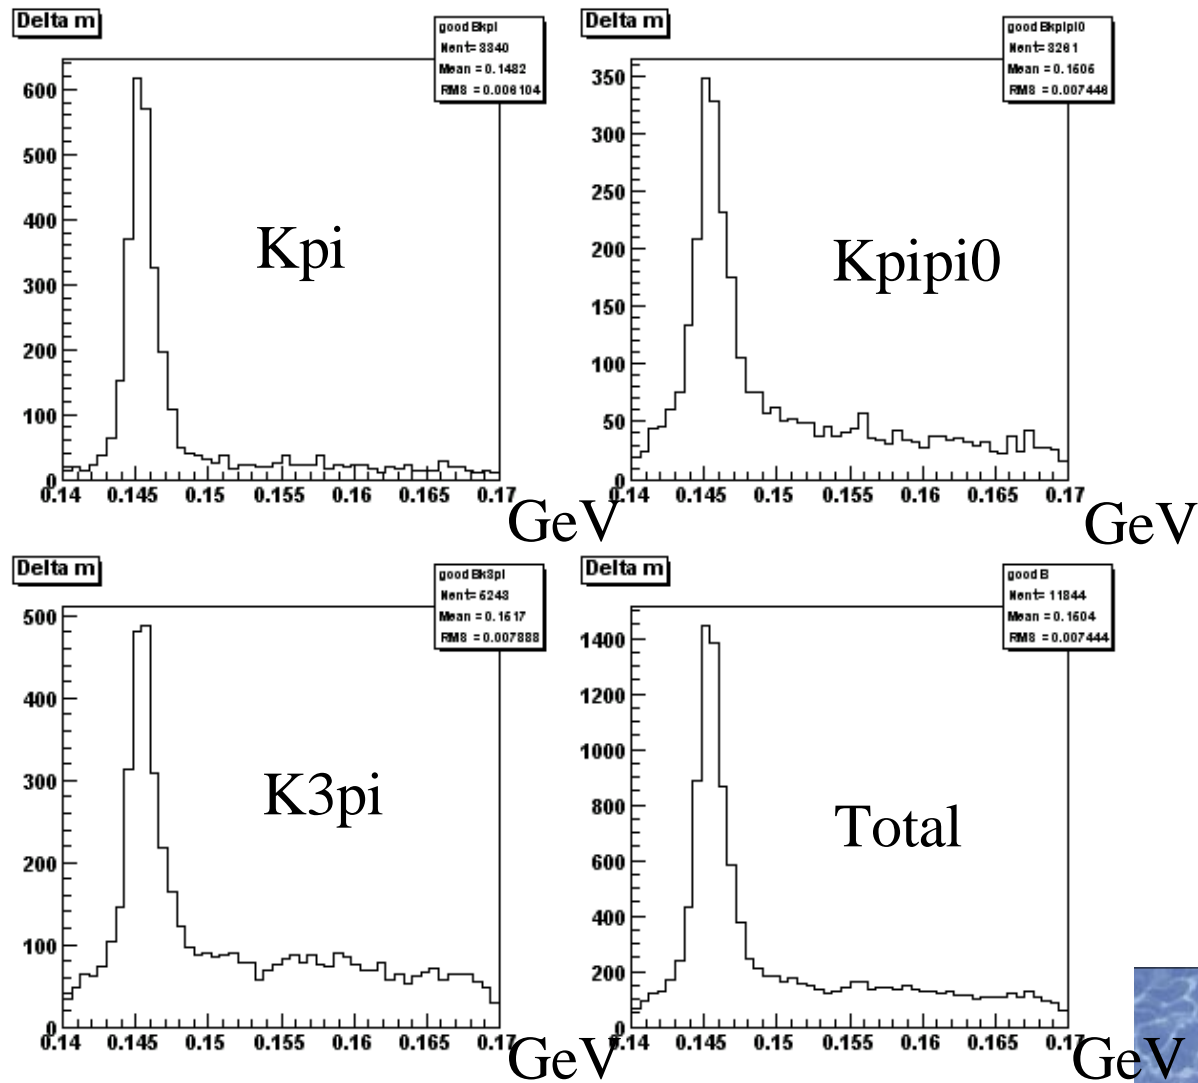

New cuts, improvements

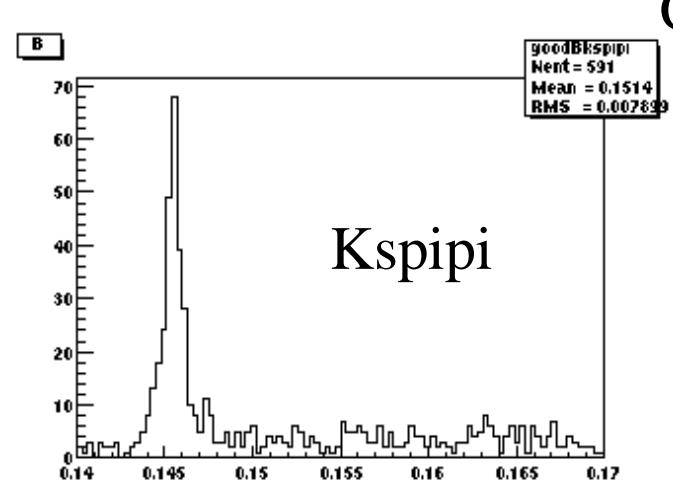

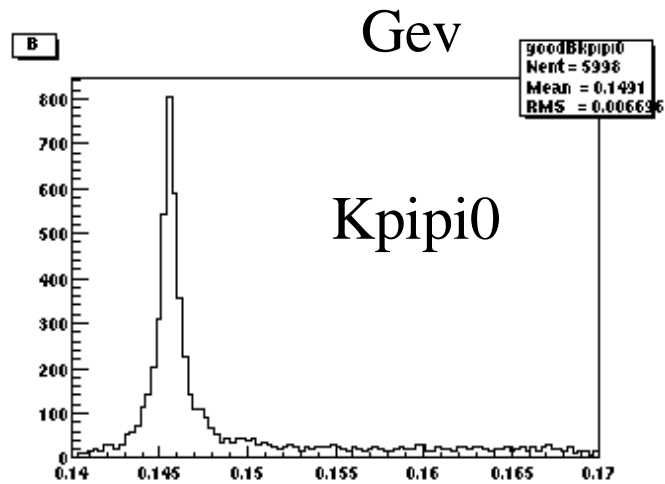

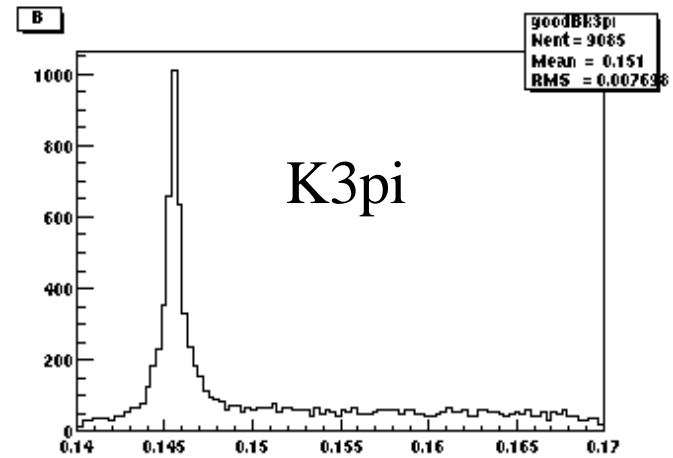

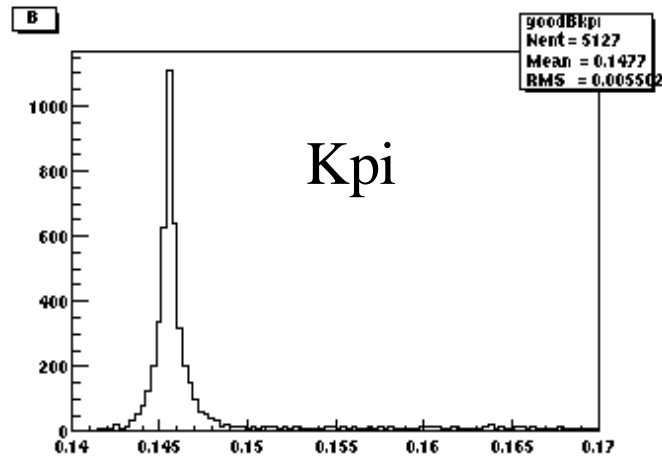

1. Very Tight lepton ID vs Tight
2. SMS Tight Kaon ID vs loose, Not a Pion for $K\pi$
3. Tighter D^0 mass cut (± 17 MeV, 34 for $K\pi\pi^0$)
4. Dalitz weight cut for $K_s\pi\pi$ and $K\pi\pi^0$ modes.
5. Deltam refitting for slow pion

$D^* - D0$ mass, good D^*l candidates (old cuts)

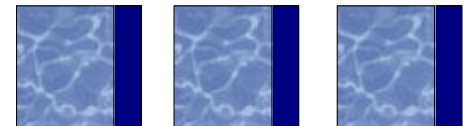

D*-D0 mass, new cuts

3 Backgrounds

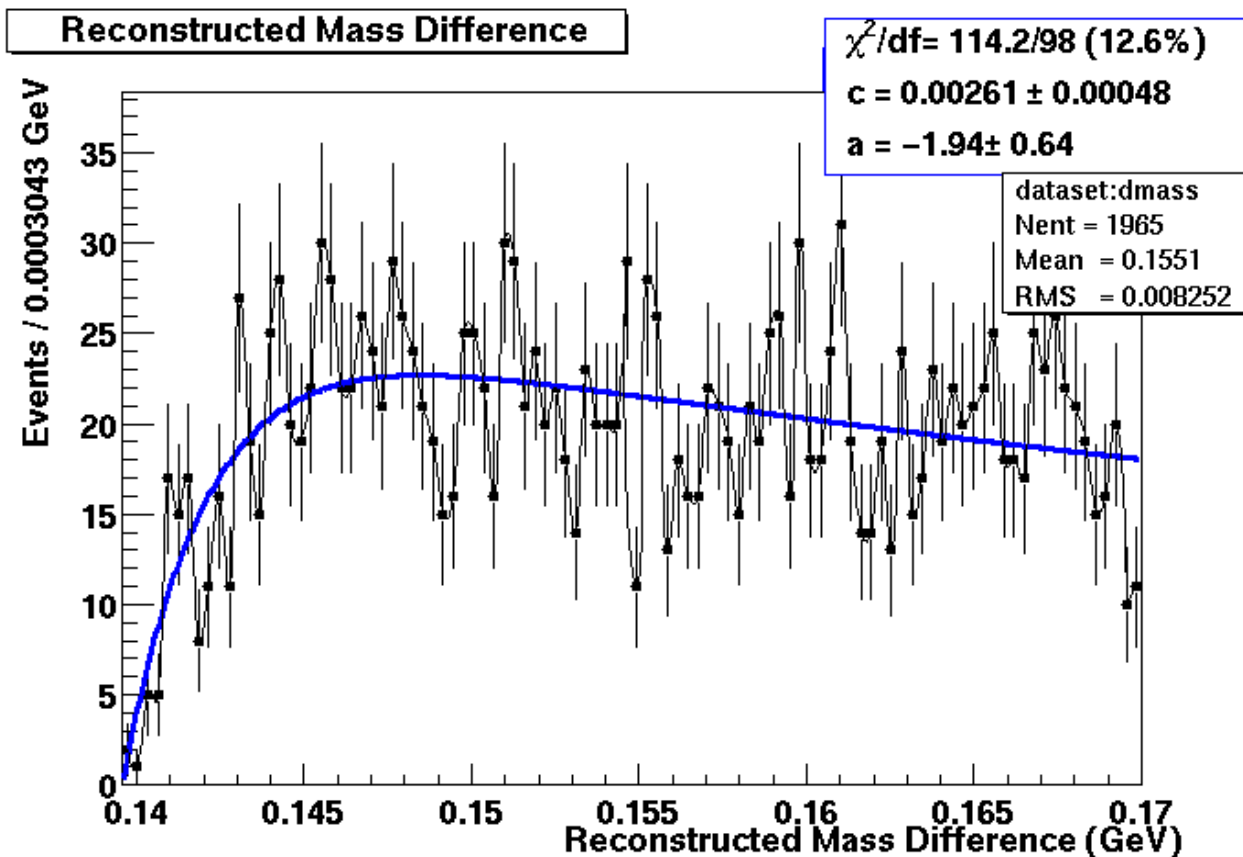

There are 5 main backgrounds we need to address:

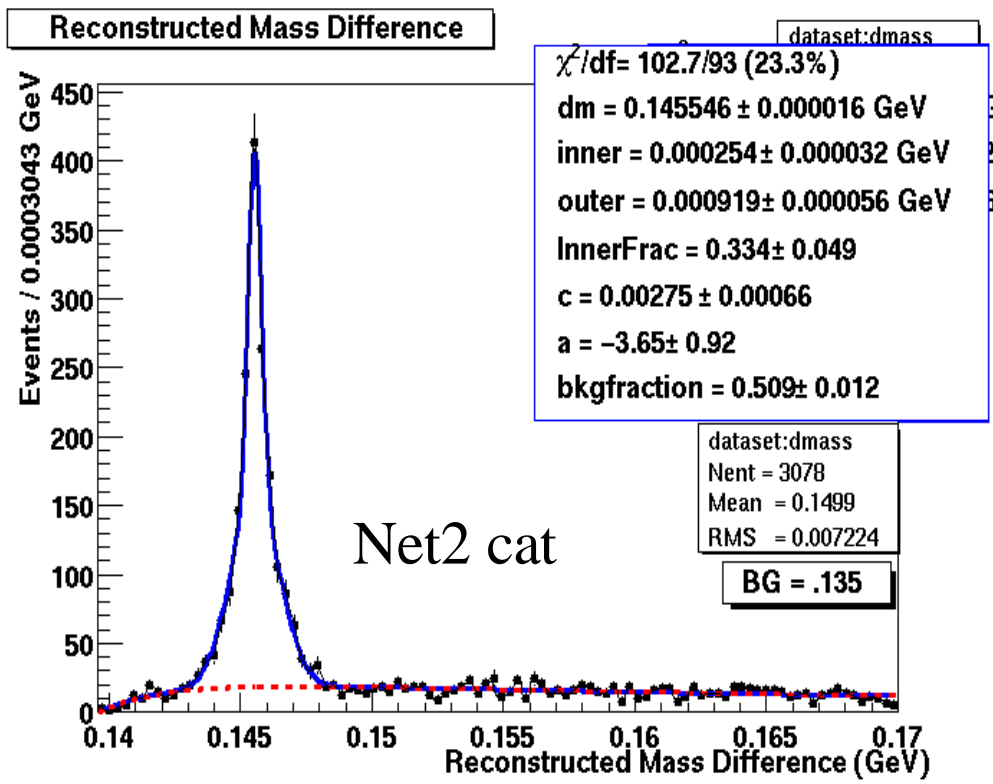

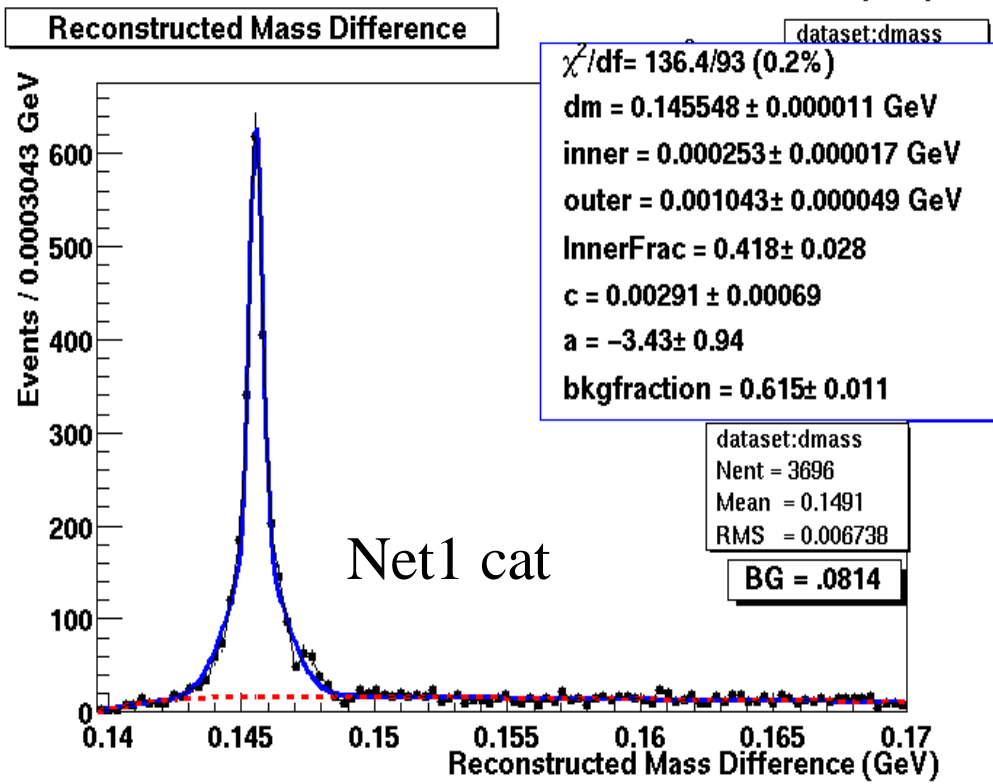

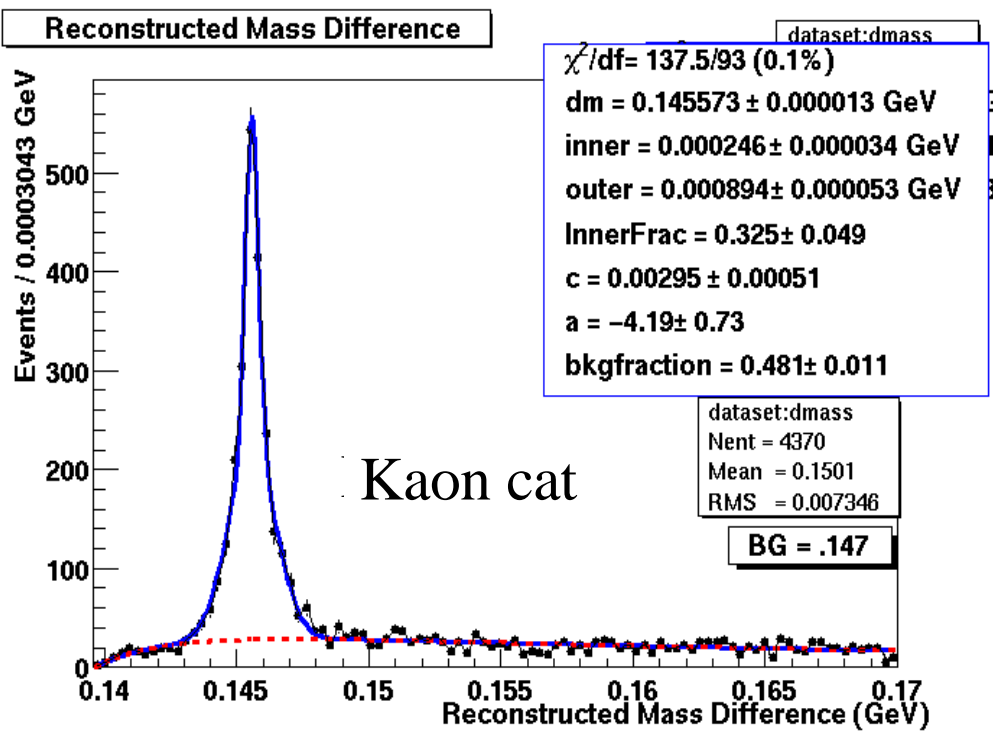

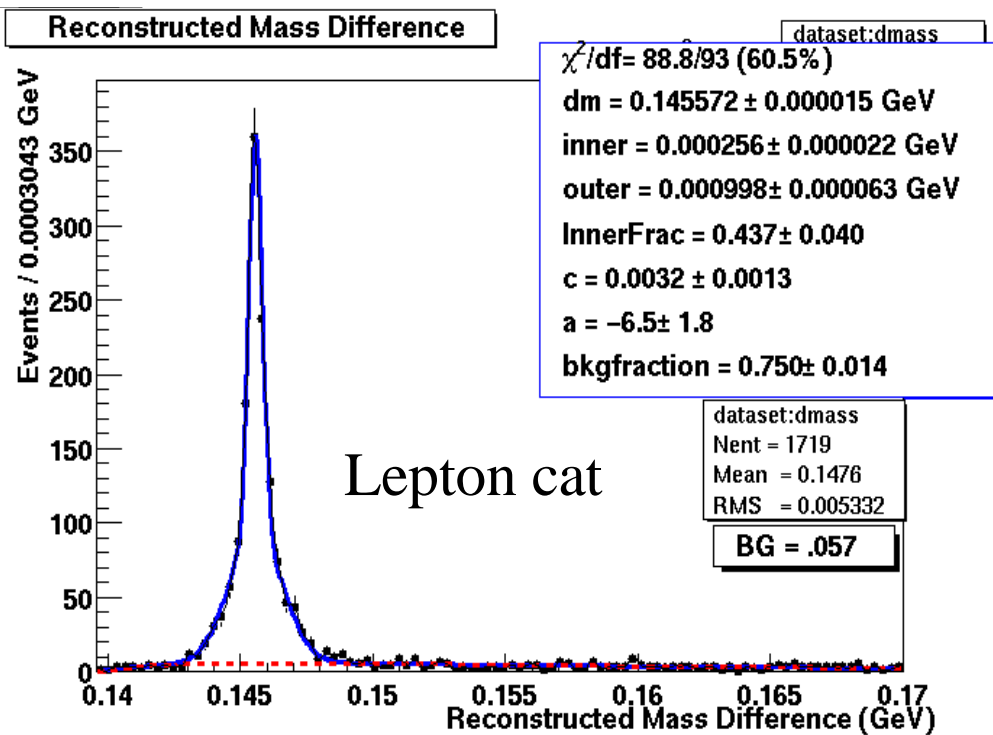

- 1) Combinatoric – Bad Dstar – either the slow pion is wrong or one of the D0 daughters is wrong
- 2) Fake Lepton – Good Dstar, bad lepton.
- 3) Uncorrelated/Cascade Lepton – Good Dstar, good lepton but they don't form a real B0
- 4) CCbar – these events can produce a Dstar and lepton in a back to back configuration
- 5) Charged Bs – can produce D^*lv through a D^{**} resonance.

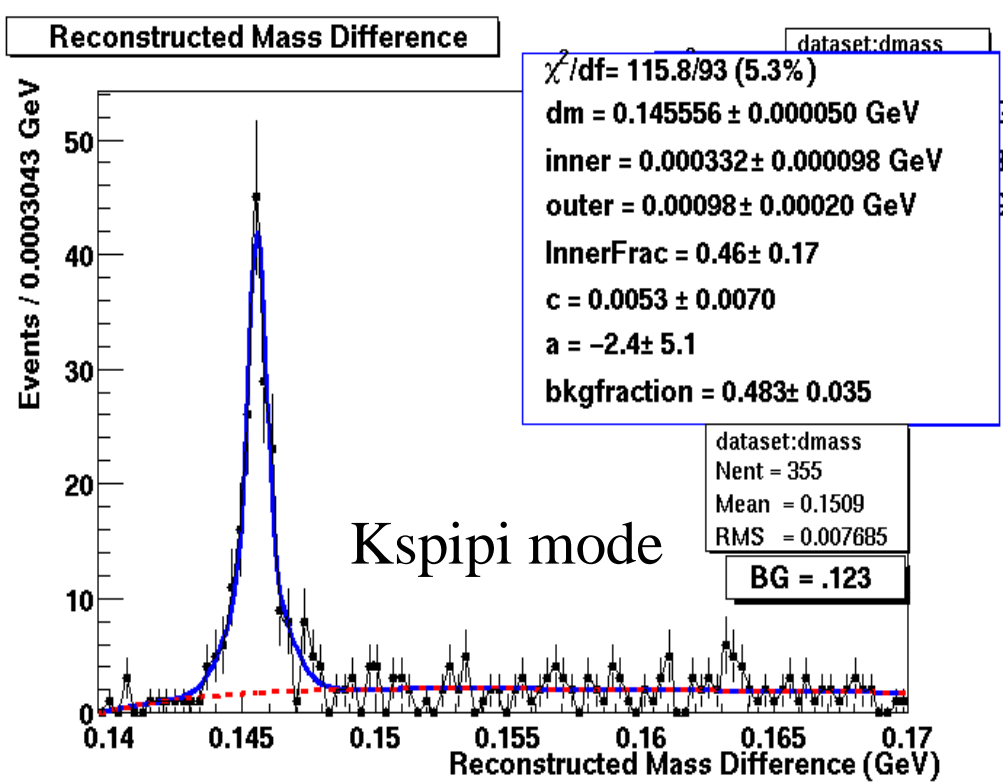

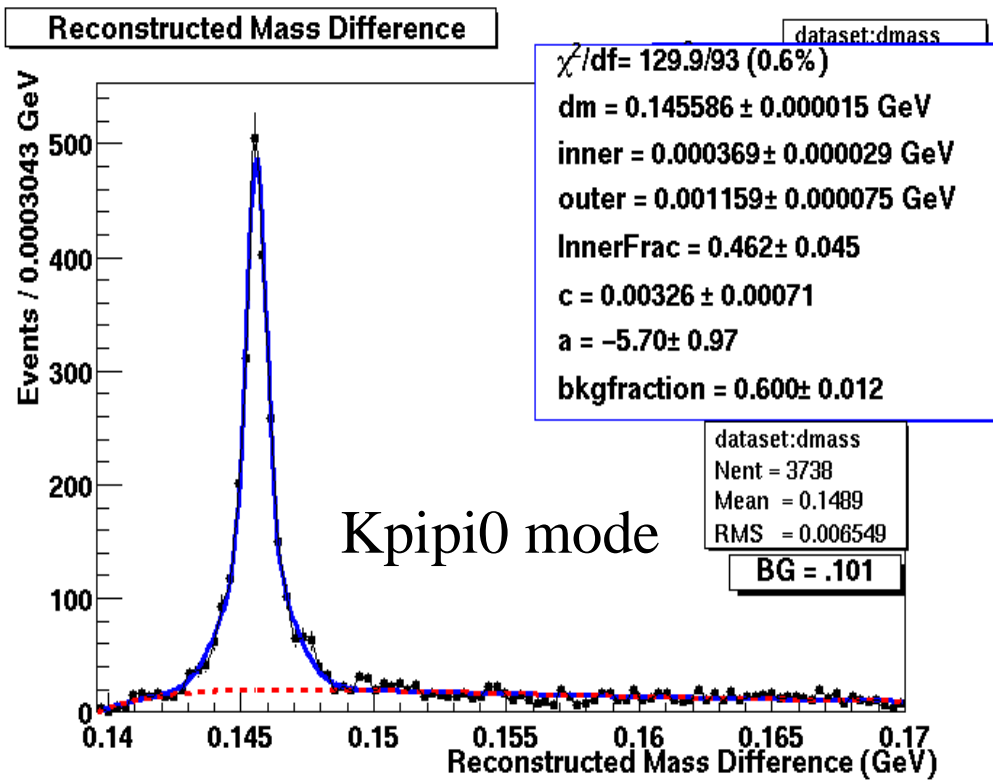

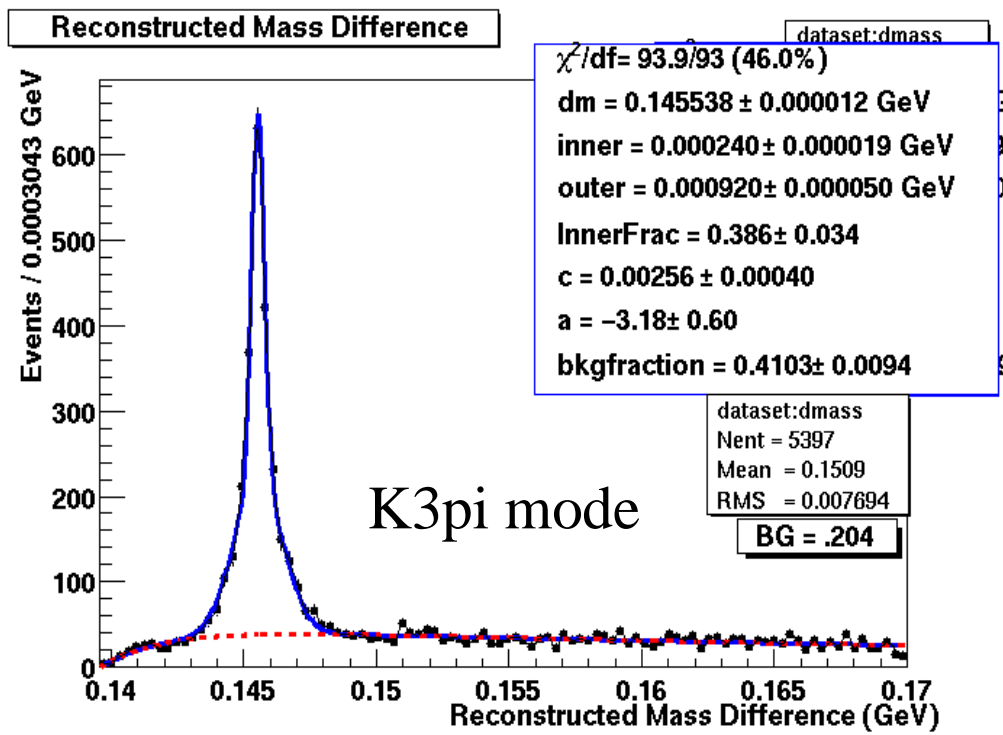

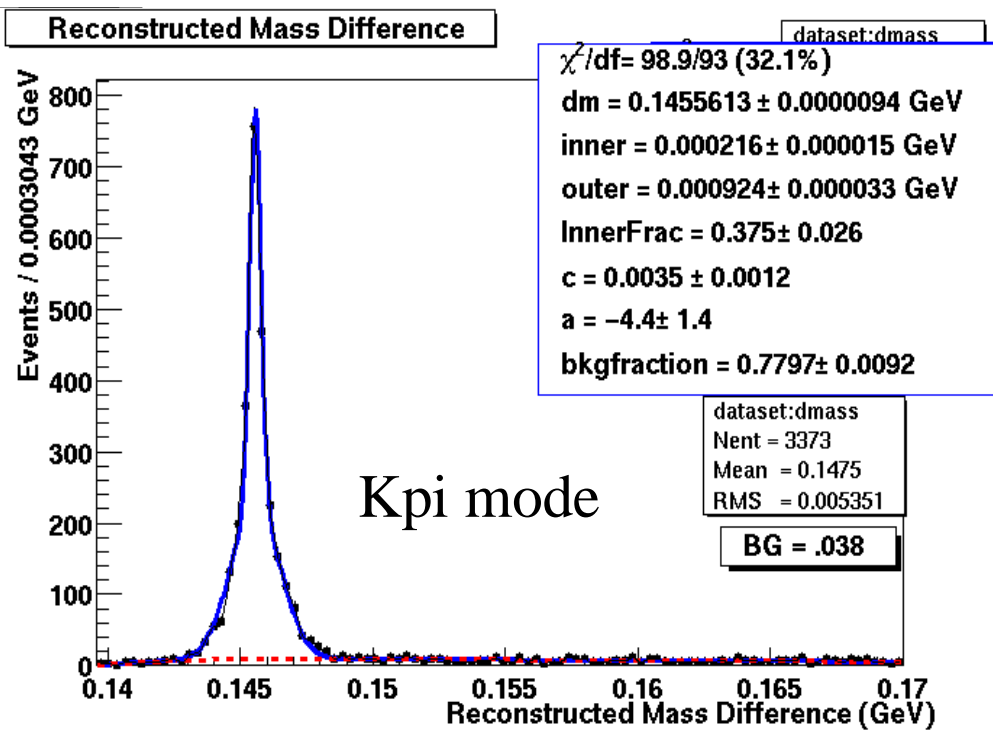

Combinatoric Backgrounds

The signal is fitted as a double Gaussian, the background is fitted as $(1 - \exp(-(m - m_{\text{pion}})/c)) * (m - m_{\text{pion}})^a$.

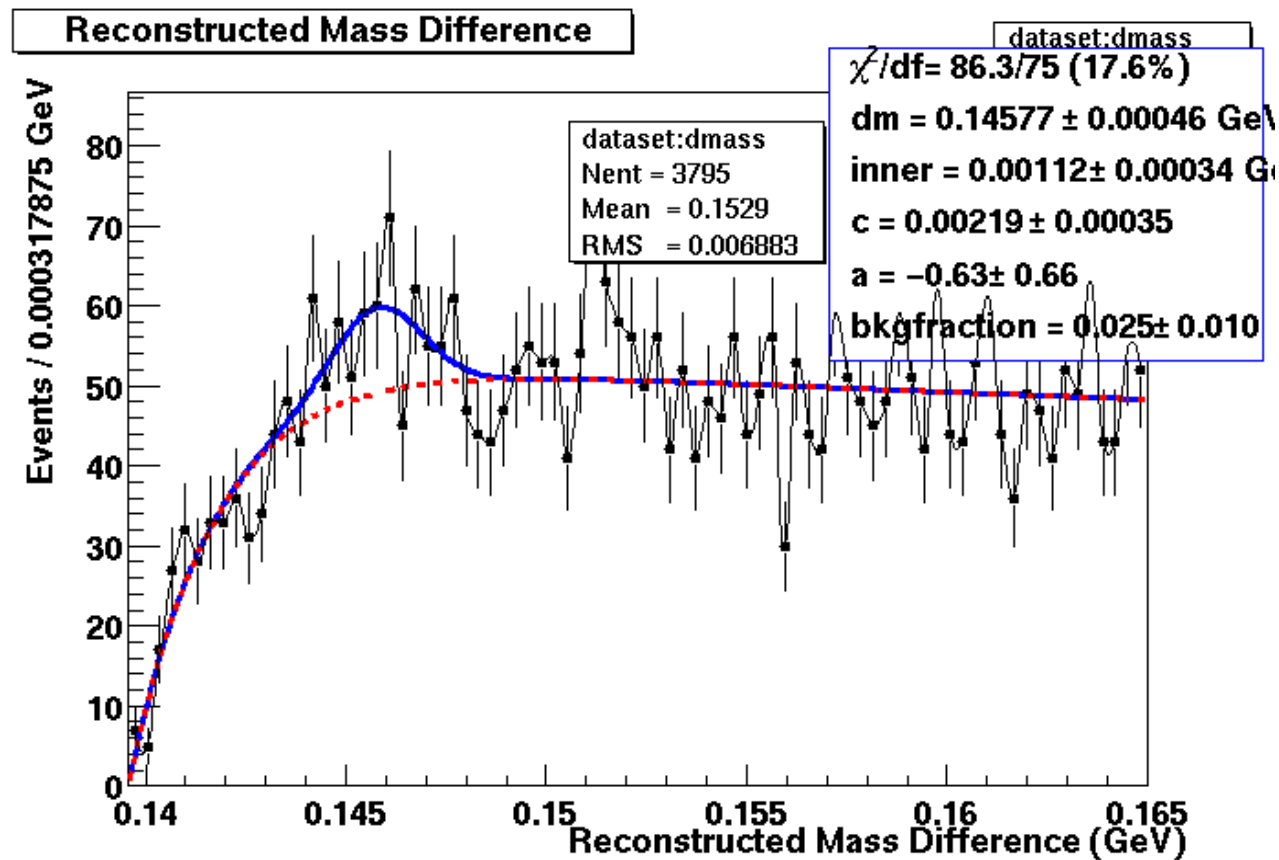

Calculated vs MC truth background fractions

	Lepton	Kaon	Net1	Net2	Kpi	K3pi	Kpipi0	Kspipi

Fake Lepton

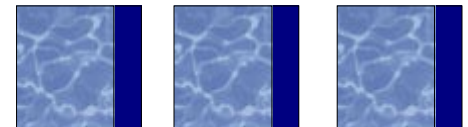

We assume that the fakes have the same time distribution as D*1 candidates that fail Lepton ID.

We calculate the lepton fake rate using the following equations:

$$N(\text{pass eid}) = Vt\text{Electron} * N(e) + Vt\text{FakeElectron}(\text{fake})$$

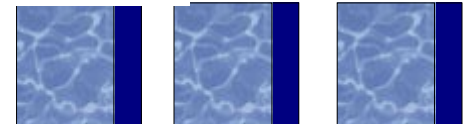

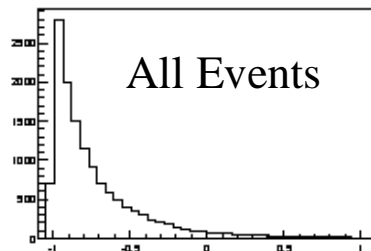

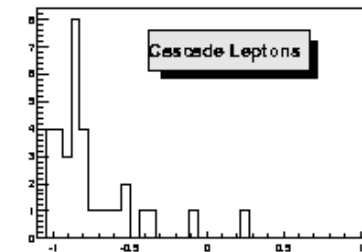

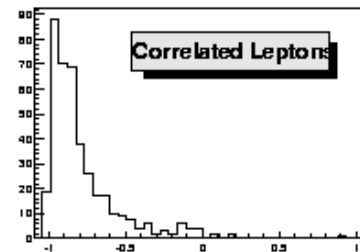

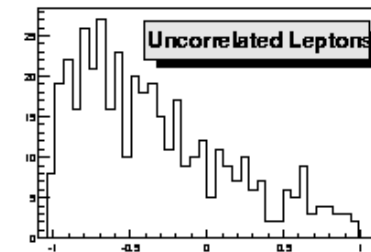

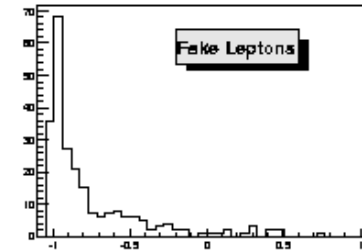

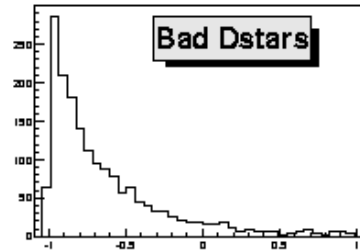

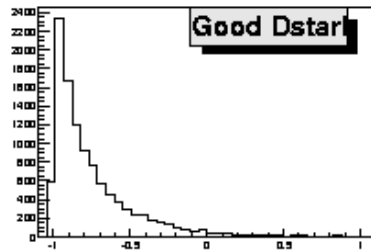

$$N(\text{pass muid}) = Vt\text{Muon} * N(\mu) + Vt\text{FakeMuon}(\text{fake})$$

$$N(\text{fail id}) = (1 - LE\text{lectron}) * N(e) + (1 - LM\text{uon}) * N(\mu) + \\ (1 - LF\text{akeElectron} - LF\text{akeMuon}) * N(\text{fake})$$

Different failure modes of D^*l 's

All cuts except $\cos(D^*l)$ are applied

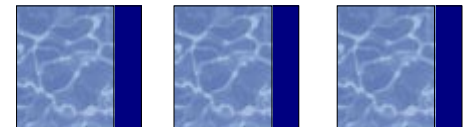

Uncorrelated/Cascade Leptons

Uncorrelated leptons come from the other B0 and should have no angular correlation with our real D* (until we make our angular cuts).

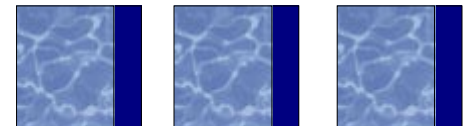

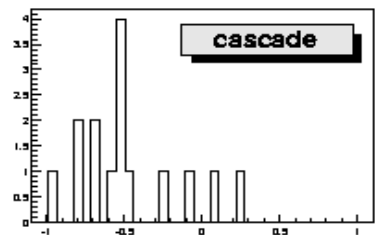

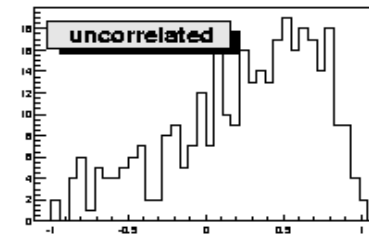

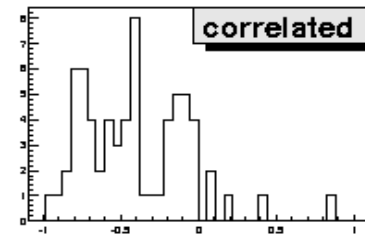

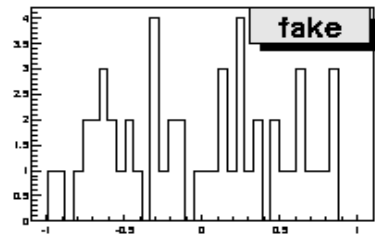

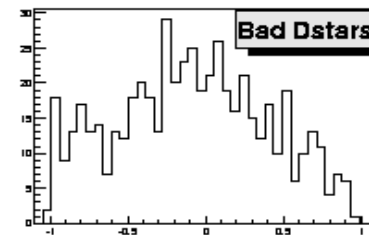

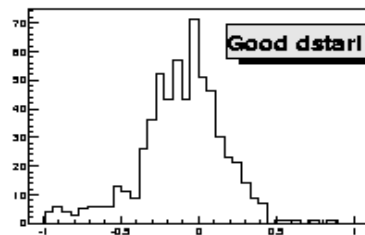

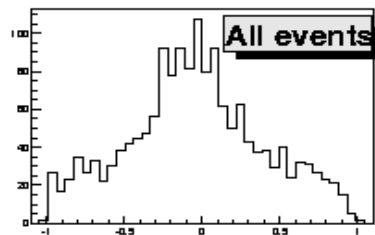

Cascade leptons should be mostly eliminated by the high lepton momentum cut.

	All Cuts	Good D*I	Bad D*	Fake	Correlated	Uncorrelated	Cascade
All $\cos(D^*l)$	12200	9843	1348	218	379	382	30
$\cos(D^*l) < 0$	11726	9561	1255	207	374	300	29
$\cos(D^*l) > 0$	474	282	93	11	5	82	1

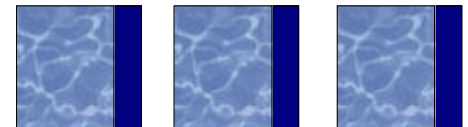

$\cos(D^*l)$ in flip lepton sample

All standard cuts applied except $\cos(D^*l)$ and $\cos\theta_{Y\text{flip}}$ vice $\cos\theta_Y$

Flip Lepton optimization of $\cos(D^*l)$ cut

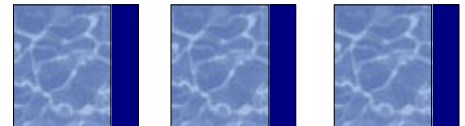

$\cos(D^*l)$	$S_2/(S+B)$	Unassociated Lepton fraction	# Unassociated Lepton Events

0.50	52.8	0.701	75

CC bar

CCbar estimates are made from offpeak data

1. Run code on offpeak data
2. Run code over Monte Carlo ccbar events
3. Verify MC matches, use MC to get idea of amounts of fake lepton, combinatoric backgrounds in offpeak data

Charged Bs

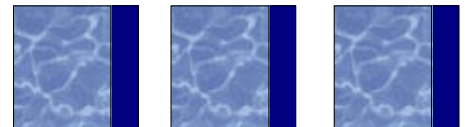

Charged Bs are devious. They can decay like:

$$B^+ \rightarrow D^{**} l \nu, D^{**} \rightarrow D^* + n \text{ soft pions}$$

"soft pion" = very low momentum pion

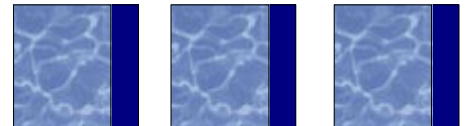

We can easily find a real D^* vertexing with a soft pion and lepton (a good $D^* l$ candidate) and all we missed was an extra soft pion which has no detectable effects.

This background fraction floats and is fitted for.

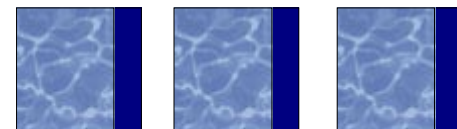

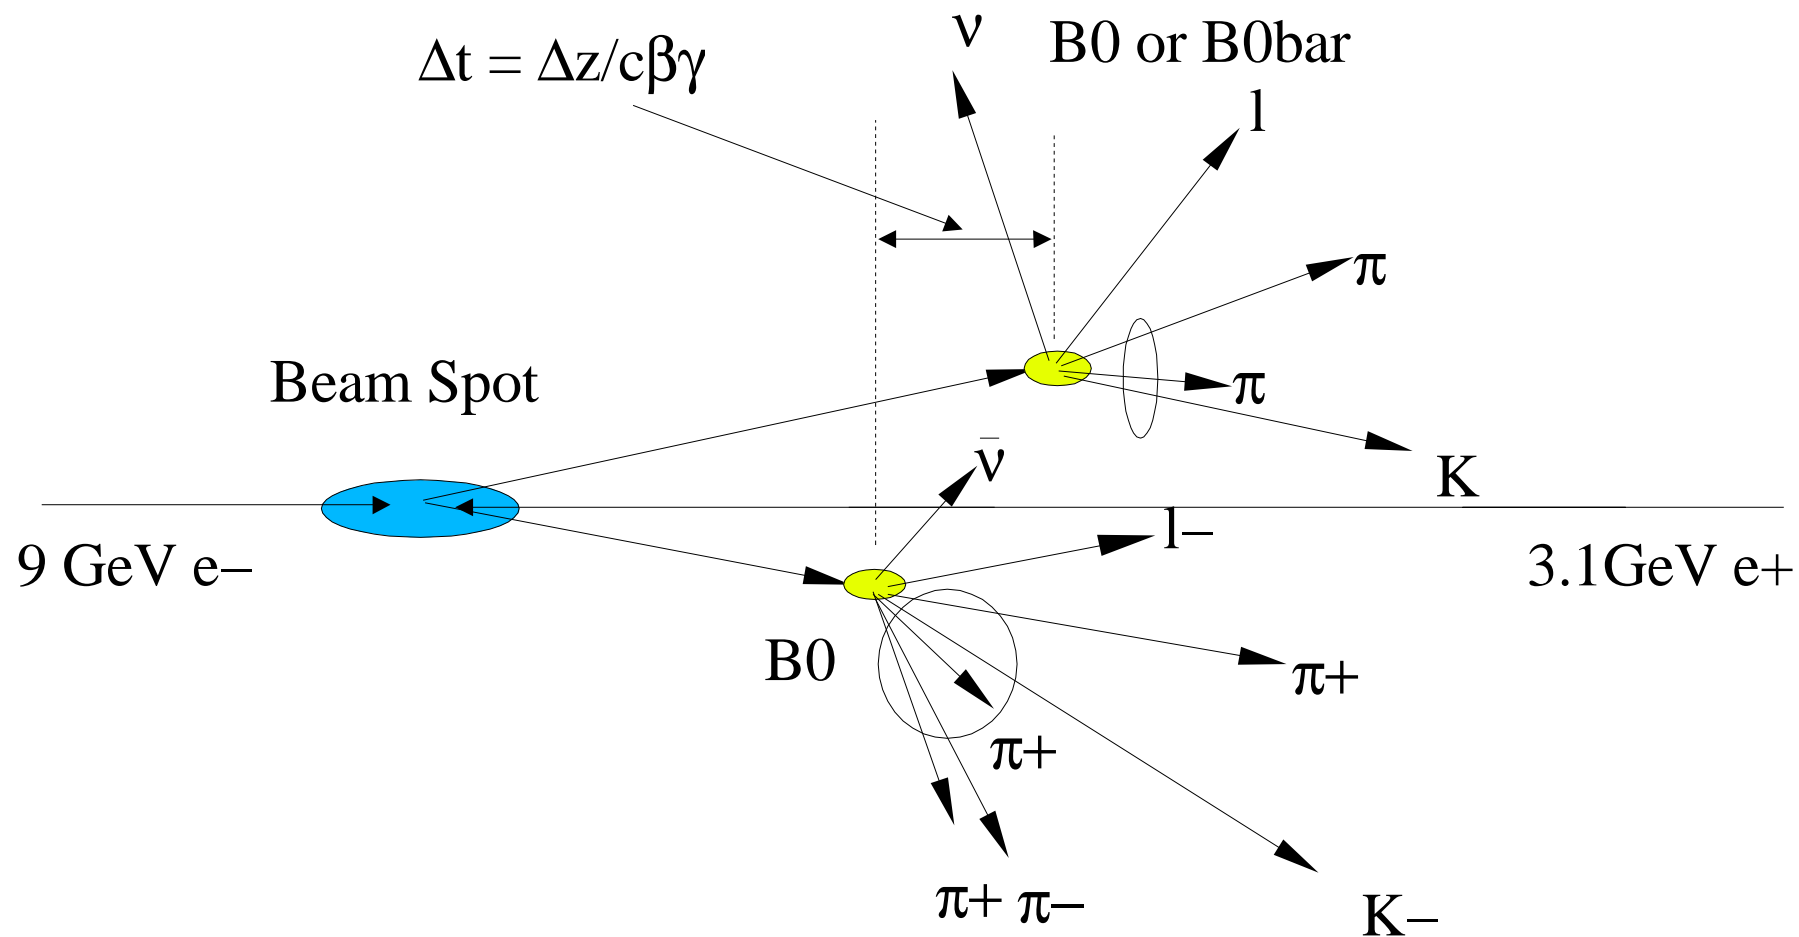

Minor backgrounds

- 1) uds – no Monte Carlo uds events pass our cuts.
- 2) These events would be taken care of by the offpeak data if they did pass our cuts.

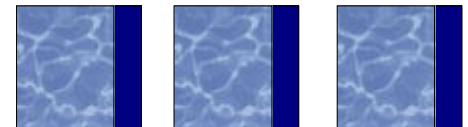

Tagging

4 Fitting for Δm

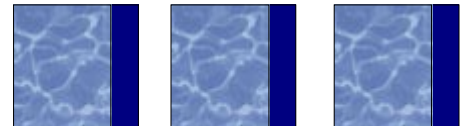

1. I am using an unbinned maximum likelihood fit, based on Δt , Δt_{error} and mixing status
 1. Uses Probability Distribution Functions (PDFs)
 2. Signal and backgrounds are built up from basic building blocks.
3. PDFs used for analysis:
 1. Dstar background
 2. Blifetime (zero and non-zero lifetimes)
 3. Mixed and unmixed B^0 decay
 4. Triple Gaussian resolution function

Fitting for background

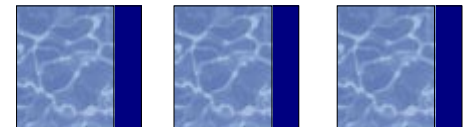

For each background:

1. Fit for background fraction
2. Fit sideband data for three types of time structure (convoluted with a resolution function)
 1. A prompt component with zero life time
 2. A B lifetime component
 3. A B lifetime component with mixing

Final Fit

1. Fix all the background parameters to their fitted values, including resolution function parameters.
2. Fit for a B lifetime with mixing component + B lifetime without mixing + fixed backgrounds (Blifetimes are allowed to float).
3. Fraction of with mixing/without mixing gives a measurement of B+ background.

List of fit parameters

1) Universal parameters

- 1) "zero" – used for prompt lifetime, zero frequency
- 2) 3 outlier parameters for background pdfs

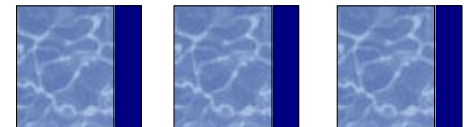

2) Backgrounds (x3)

- 1) 5 more resolution parameters for triple gaussian
- 2) 6 "physics" – dm, tau, w, p frac, B+ frac, back frac

3) Signal

- 1) 8 resolution parameters (frac, width outlier fixed)
- 2) 6 "physics" – dm, tau, w, tauB+, wB+, B+ frac
 - 1) WB+ fixed from MC truth, all others float

4) Totals: 51 parameters, 11 float in final fit

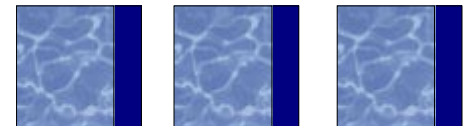

Fit values

Here are the fit values, several issues are present which need to be readdressed

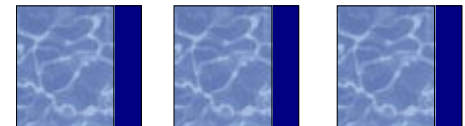

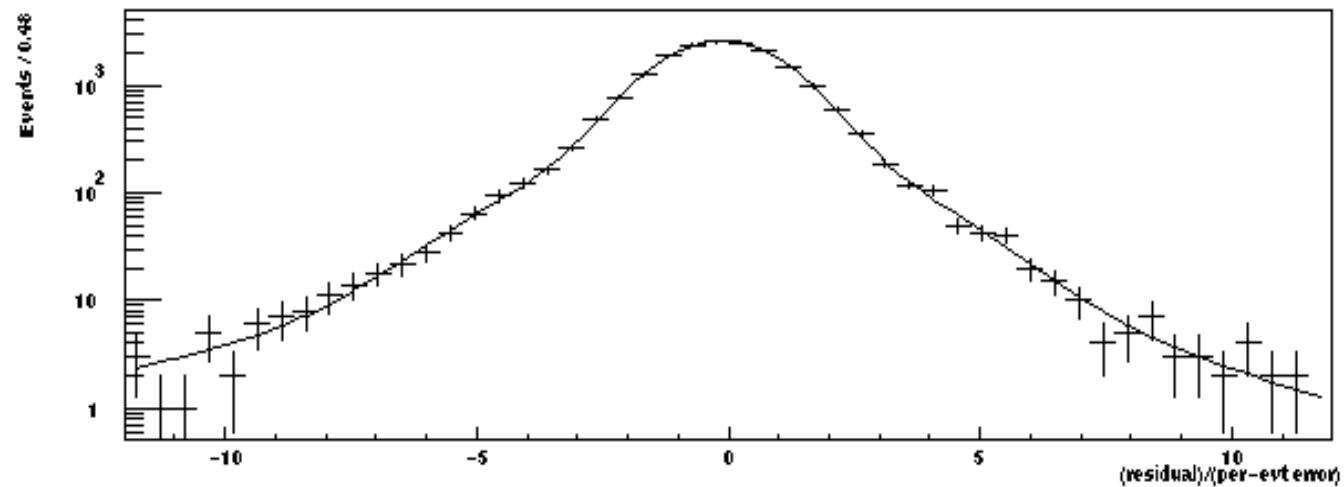

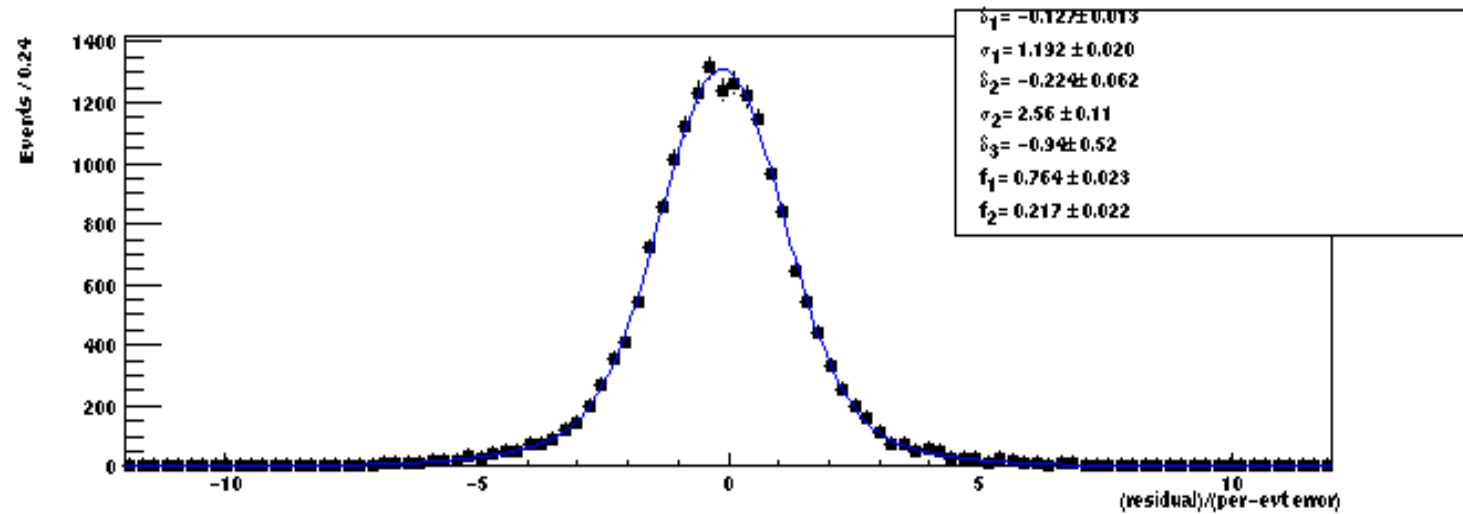

– Signal outlier bias, Flip lepton sample, B+ fraction

MC generated with $\Delta m = .472 \text{ ps}^{-1}$, $\tau = 1.548 \text{ ps}$

	Lepton	Kaon	Net1	Net2	Combined
Δm	.446 +/- .031	.426 +/- .051	.482 +/- .033	.488 +/- .152	.459 +/- .020
τ	1.593 +/- .081	1.548 +/- .358	1.59 +/- .387	1.76 +/- .237	1.62 +/- .074
<hr/> w	.055 +/- .018	.210 +/- .060	.096 +/- .025	.311 +/- .041	
MC truth w	.056 +/- .007	.212 +/- .010	.124 +/- .007	.336 +/- .014	
<hr/> B+ fraction	.25 +/- .15	.001 +/- .15	.034 +/- .18	.35 +/- .32	
MC truth B+	.049 +/- .0062	.086 +/- .0061	.073 +/- .0056	.065 +/- .0062	

Pull distribution for background events

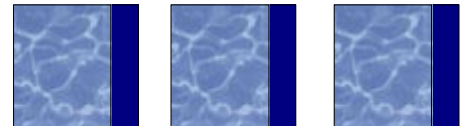

Pull distribution for signal events

To Do List

- 1) Add ccbar component for off-peak data
- 2) Work on isolating the "flip lepton" part of flip lepton sample.
- 3) Add blinding strings to RooFitTools macros so I can work "blind" on data.
- 4) Look at outliers in more detail
- 5) Produce list of systematics and cross checks to be done, complete checks.
- 6) Write BAD note documentation

Systematics and Cross Checks

Systematics

- 1) MC generic & signal
- 2) Resolution function
- 3) B lifetime
- 4) Z Scale, boost
- 5) Beam position
- 6) Background Dt
- 7) Background Res function
- 8) Background fractions
- 9) Beamspot Position
- 10) Dilutions
- 11) SVT Alignment

Cross Checks

- 1) B0 vs B0bar
- 2) D0 decay mode
- 3) Tagging category
- 4) Different Resolution Models
- 5) B lifetime studies
- 6) Dataset
